Chrome verified that Symantec Class 3 Secure Server CA - G4 issued this website's certificate. The server did not supply any Certificate Transparency information.

[Certificate Information](#)

Your connection to www.amazon.com is encrypted using a modern cipher suite.

The connection uses TLS 1.2.

The connection is encrypted and authenticated using AES_128_GCM and uses ECDHE_RSA as the key exchange mechanism.

What is Cryptography?

Cryptography involves algorithms with security goals.

Cryptography involves using math to stop adversaries.

Common Security Goal: Secure Channel

Client

Server

Confidentiality: Adversary does not learn anything about messages m_1, m_2

Authenticity: $m'_1 = m_1$ and $m'_2 = m_2$

Crypto in CS23200/33250

- A brief overview of major concepts and tools
- Cover (some of) big “gotchas” in crypto deployments
- Cover background for networking and authentication later

Not going to cover math, proofs, or many details.
Consider taking CS284 (Cryptography)!

Four settings for cryptography

Security Goal Pre-shared key?	Confidentiality	Authenticity/Integrity
Yes ("Symmetric")	Symmetric Encryption (aka Secret-key Encryption)	Message Authentication Code (MAC)
No ("Asymmetric")	Public-Key Encryption	Digital Signatures

Rest of this lecture

- Symmetric Encryption Basics
- Stream Ciphers

Rest of this lecture

- **Symmetric Encryption Basics**
- Stream Ciphers

Ciphers (a.k.a. Symmetric Encryption)

A cipher is a pair of algorithms Encrypt, Decrypt:

Require that decryption recovers the same message.

Historical Cipher: ROT13 (“Caesar cipher”)

Encrypt(K,m): shift each letter of plaintext forward by K positions in alphabet (wrap from Z to A).

Plaintext: **DEFGH**

Key (shift): 3

Ciphertext: **FGHKL**

Plaintext: **ATTACKATDAWN**

Key (shift): 13

Ciphertext: **NGGNPXNGQNJJA**

Historical Cipher: Substitution Cipher

Encrypt(K,m): Parse key K as a permutation π on $\{A, \dots, Z\}$.
Apply π to each character of m.

P: ATTACKATDAWN

K: π 

C: ZKKZAMZKYZGT

x	$\pi(x)$
A	Z
B	U
C	A
D	Y
E	R
F	E
G	X
H	B
I	D
J	C
K	M
L	Q
M	H
N	T
O	I
P	S
Q	V
R	N
S	P
T	K
U	O
V	F
W	G
X	W
Y	L
Z	J

How many keys?

$$26! \approx 2^{88}$$

9 million years to try all keys at rate of
1 trillion/sec

Cryptanalysis of Substitution Cipher

CELEBRITY CIPHER
by Luis Campos

Celebrity Cipher cryptograms are created from quotations by famous people, past and present.
Each letter in the cipher stands for another.

“ U P X E G T H W Z H F X Y L F H O S L N P F X . H M
T P J S X E P O X V P G A V G P O S L E E B X X O A
P M L N P F X , T P J ' C X Z P W E E B X V B P Z X
E B H O S . ” — V . W . Y X G V H O

Previous Solution: “Time is the cruelest teacher; first she gives the test, then teaches the lesson.” — Leonard Bernstein

TODAY'S CLUE: r sjænbə N

© 2012 by NEA, Inc., dist. by Universal Uclick 9-20

Quick recall: Bitwise-XOR operation

We will use bit-wise XOR:

$$\begin{array}{r} 0101 \\ \oplus 1100 \\ \hline 1001 \end{array}$$

Some Properties:

- $X \oplus Y = Y \oplus X$
- $X \oplus X = 000\dots 0$
- $X \oplus Y \oplus X = Y$

Cipher Example: One-Time Pad

Key K: Bitstring of length L

Plaintext M: Bitstring of length L

Encrypt(K,M): Output $K \oplus M$

Decrypt(K,C): Output $K \oplus C$

Example:

$$\begin{array}{r} 0101 \\ \oplus 1100 \\ \hline 1001 \end{array}$$

Correctly decrypts because

$$K \oplus C = K \oplus (K \oplus M) = (K \oplus K) \oplus M = M$$

Q: Is the one-time pad secure?

Bigger Q: What does “secure” even mean?

Evaluating Security of Crypto Algorithms

Kerckhoff's Principle: Assume adversary knows your algorithms and implementation. The only thing it doesn't know is the key.

1. Quantify adversary goals

Learn something about plaintext? Spoof a message?

2. Quantify adversary capabilities

View ciphertexts? Probe system with chosen inputs?

3. Quantify computational resources available to adversary

Compute cycles? Memory?

Breaking Encryption - A Basic Game

Ciphertext-only attack: The adversary sees ciphertexts and attempts to recover some useful information about plaintexts.

More attack settings later.

Recovering Partial Information; Partial Knowledge

- Recovering entire messages is useful
- But recovering **partial information** is also be useful

A lot of information is missing here.

But can we say who this is?

- Attacker may know large parts of plaintext already (e.g. formatting strings or application content). The attacker tries to obtain something it doesn't already know.

`M = http://site.com?password=` ████████████████████

“Attacks” versus “Security”

An **attack** is successful as long as it recovers some info about plaintext that is useful to adversary.

Encryption should hide all possible partial information about plaintexts, since what is useful is situation-dependent.

Attacks can succeed without recovering the key

Full break: Adversary recovers K , decrypts all ciphertexts.

However: Clever attacker may compromise encryption without recovering the key.

Security of One-Time Pad

Claim: If adversary sees **only one** ciphertext under a random key, then any plaintext is equally likely, so it cannot recover any partial information besides plaintext length.

Ciphertext observed: 10111

Possible plaintext: 00101

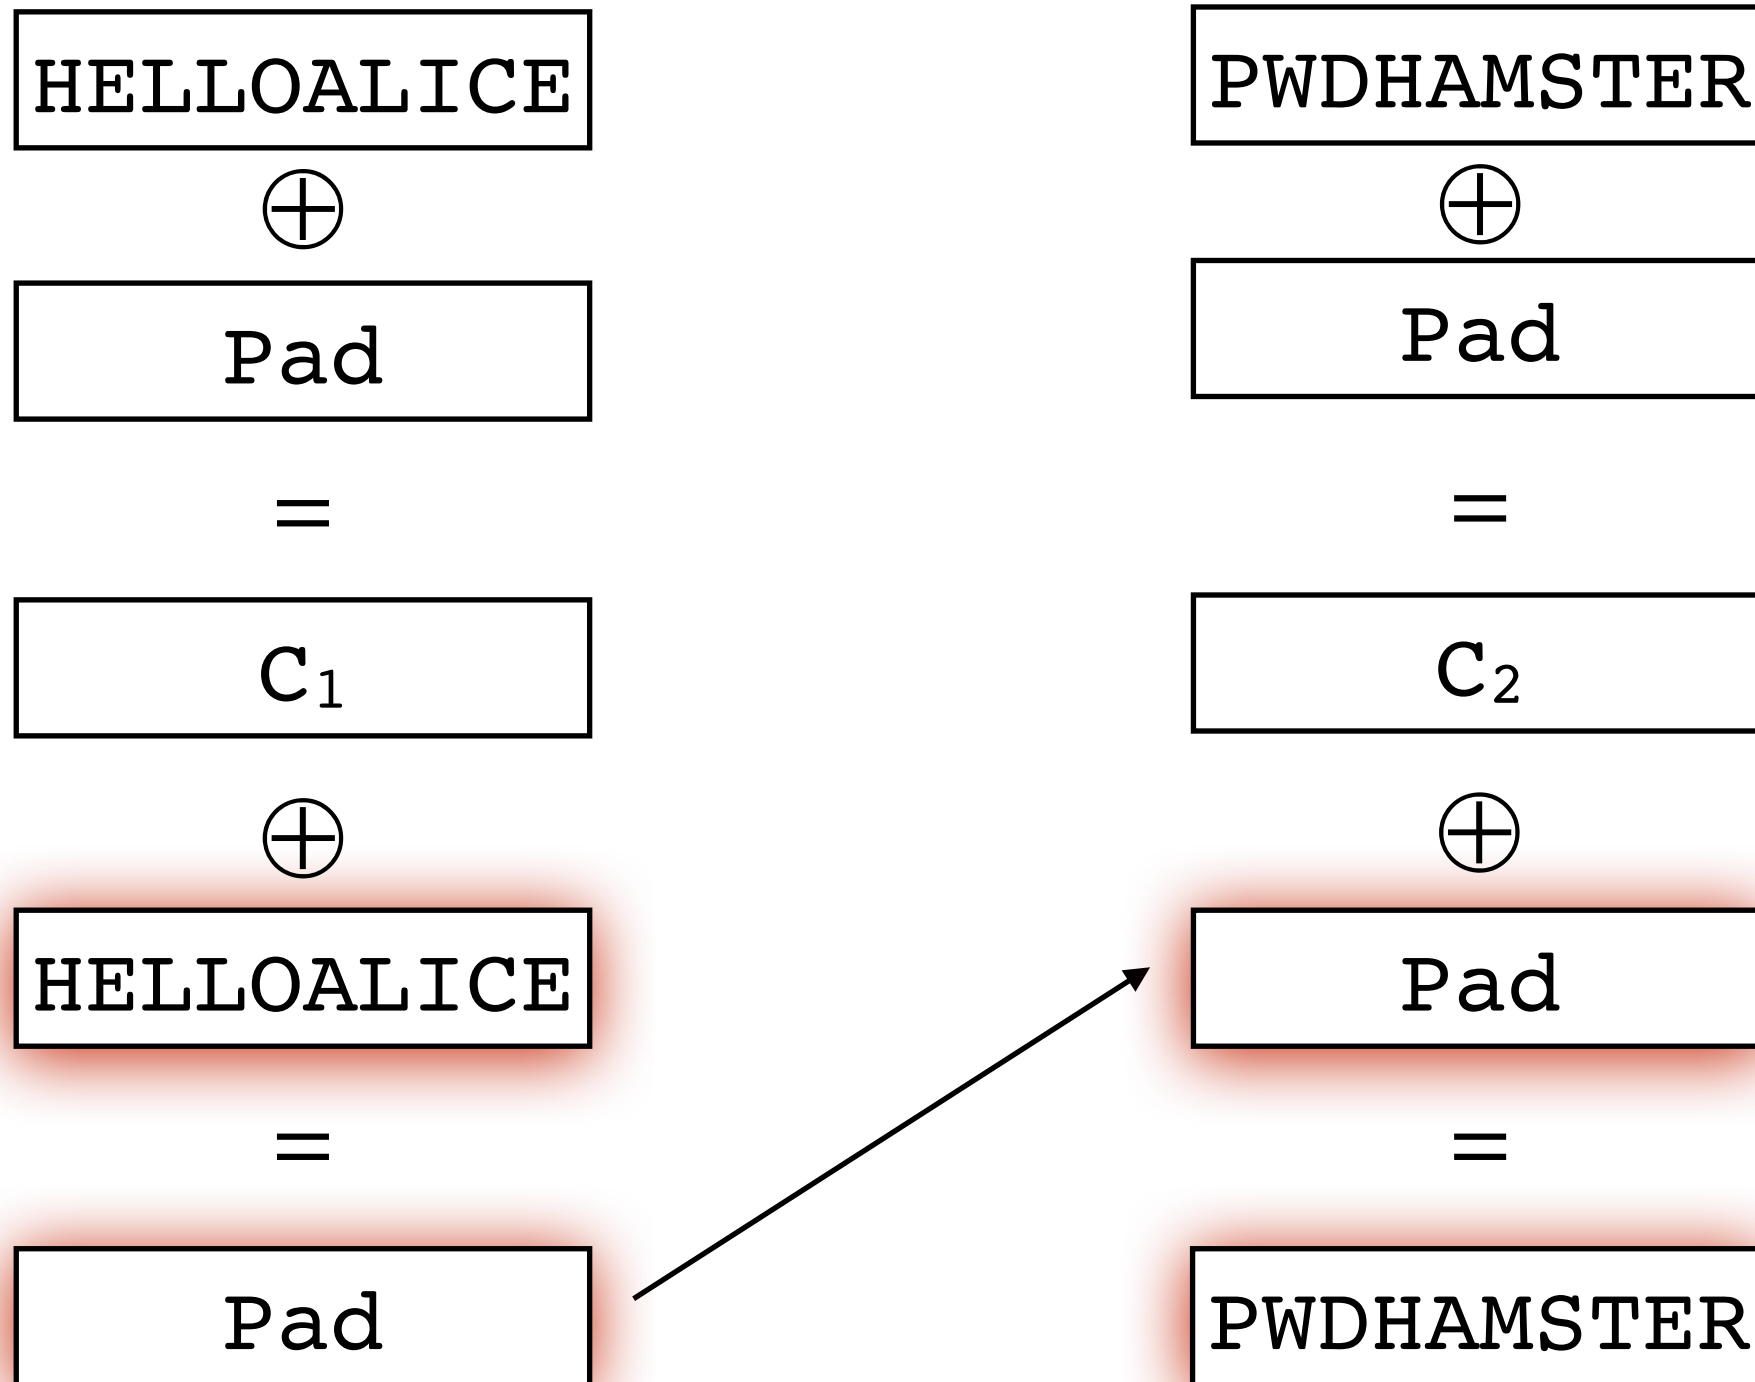

⇒ Possible key: 10010

1. Adversary goal: Learn partial information from plaintext
2. Adversary capability: Observe a single ciphertext
3. Adversary compute resources: Unlimited time/memory (!)

Issues with One-Time Pad

1. Reusing a pad is insecure
2. One-Time Pad is *malleable*
3. One-Time Pad has a long key

Issue #1: Reusing a One-Time Pad is Insecure

Issue #1: Reusing a One-Time Pad is Insecure

Has led to real attacks:

- Project Venona (1940s) attack by US on Soviet encryption
- MS Windows NT protocol PPTP
- WEP (old WiFi encryption protocol)
- Fortiguard routers! [[link](#)]

Issue #2: One-Time Pad is *Malleable*

PAYALICE\$1

Pad

=

C

⊕

000ALICE00

⊕

000DAVID00

=

C'

Decrypt(Pad, C') = PAYDAVID\$1

Issue #3: One-Time Pad Needs a Long Key

Can prove: Any cipher as secure as the OTP must have:
Key-length \geq Plaintext-length

In practice:

- Use *stream cipher*: $\text{Encrypt}(K,m) = G(K) \oplus m$
- Add *authentication tag*
- Use *nonces* to encrypt multiple messages

Outline

- Symmetric Encryption Basics
- **Stream Ciphers**
- Block Ciphers

Stream Cipher Security Goal (Sketch)

Security goal: When \mathbf{k} is random and unknown, $G(\mathbf{k})$ should “look” random.

... even to an adversary spending a lot of computation.

Much stronger requirement that “passes statistical tests”.

Brute force attack: Given $\mathbf{y}=G(\mathbf{k})$, try all possible \mathbf{k} and see if you get the string \mathbf{y} .

Clarified goal: When \mathbf{k} is random and unknown, $G(\mathbf{k})$ should “look” random to anyone with less computational power needed for a brute force attack.

(keylength = 256 is considered strong now)

Aside: Fundamental Physical Property of the Universe*

There exist (1-to-1) functions (say on bitstrings) that are:

- 1) Very fast to evaluate
- 2) Computationally infeasible to reverse

The disparity can be almost arbitrarily large!

Evaluating $y = f(x)$ may only take a few cycles....

... and finding x from y within the lifetime of the universe may not be possible, even with a computer made up of every particle in the universe.

**conjectured, but unproven property*

Computational Strength

# Steps	Who can do that many?
2^{56}	Strong computer with GPUs
2^{80}	All computers on Bitcoin network in 4.5 hours
2^{128}	Very large quantum computer? (Ask Diana,Fred,Bill,Robert)*
2^{192}	Nobody?
2^{256}	Nobody?

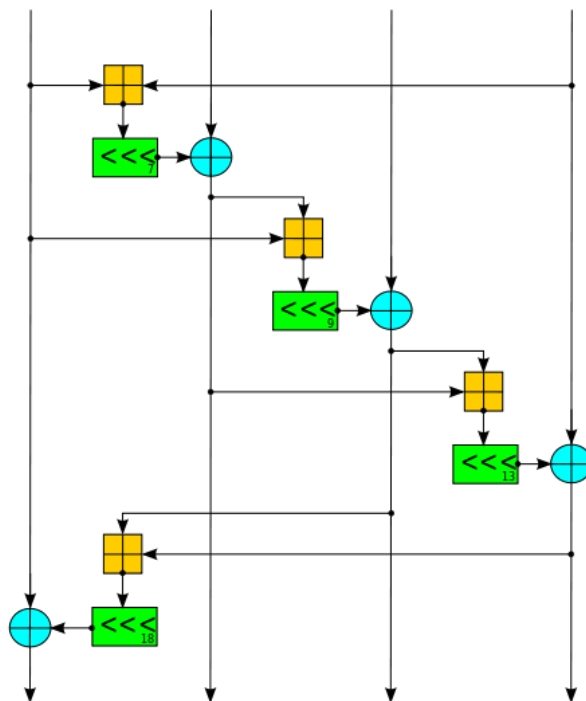

*Not directly comparable but this is an estimate of equivalent power. Quantum computers are most effective against public-key crypto, but they also speed up attacks on symmetric-key crypto. (More next time.)

Practical Stream Ciphers

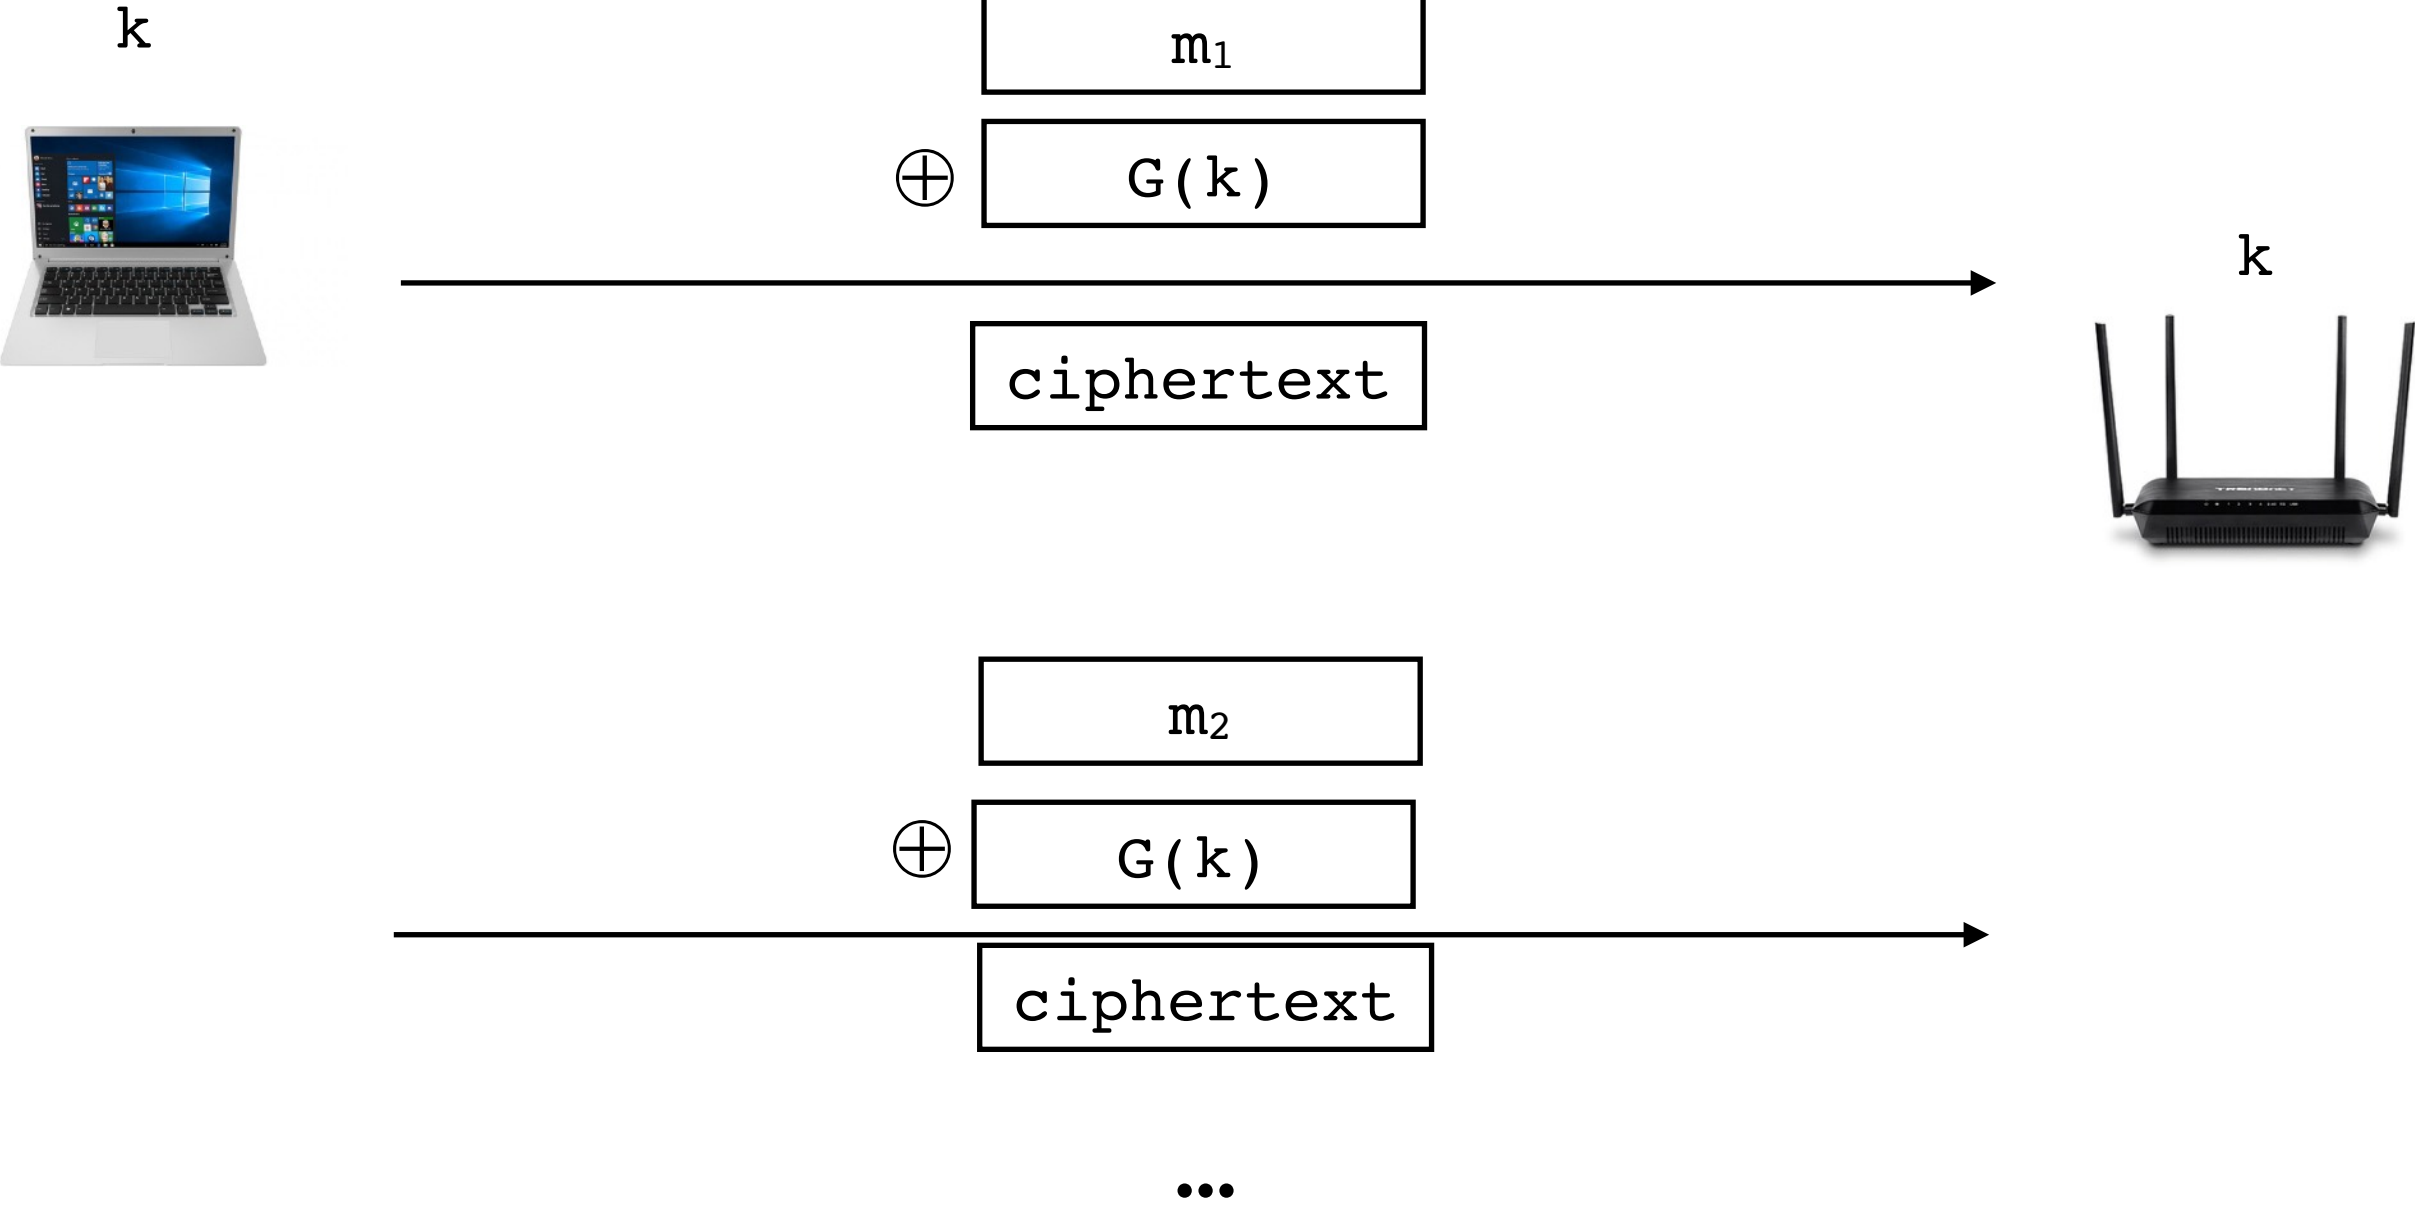

RC4 (1987): “Ron’s Cipher #4”. Mostly retired by 2016.

ChaCha20 (2007): Successfully deployed replacement.
Supports *nonces*.

Pad reuse can still happen with stream ciphers

Addressing pad reuse: Stream cipher with a nonce

Stream cipher with a nonce: Algorithm G that takes **two inputs** and produces a very long bit-string as output.

<u>Nonce IV:</u>	<u>Key/Seed k:</u>
1100...11	1100...11

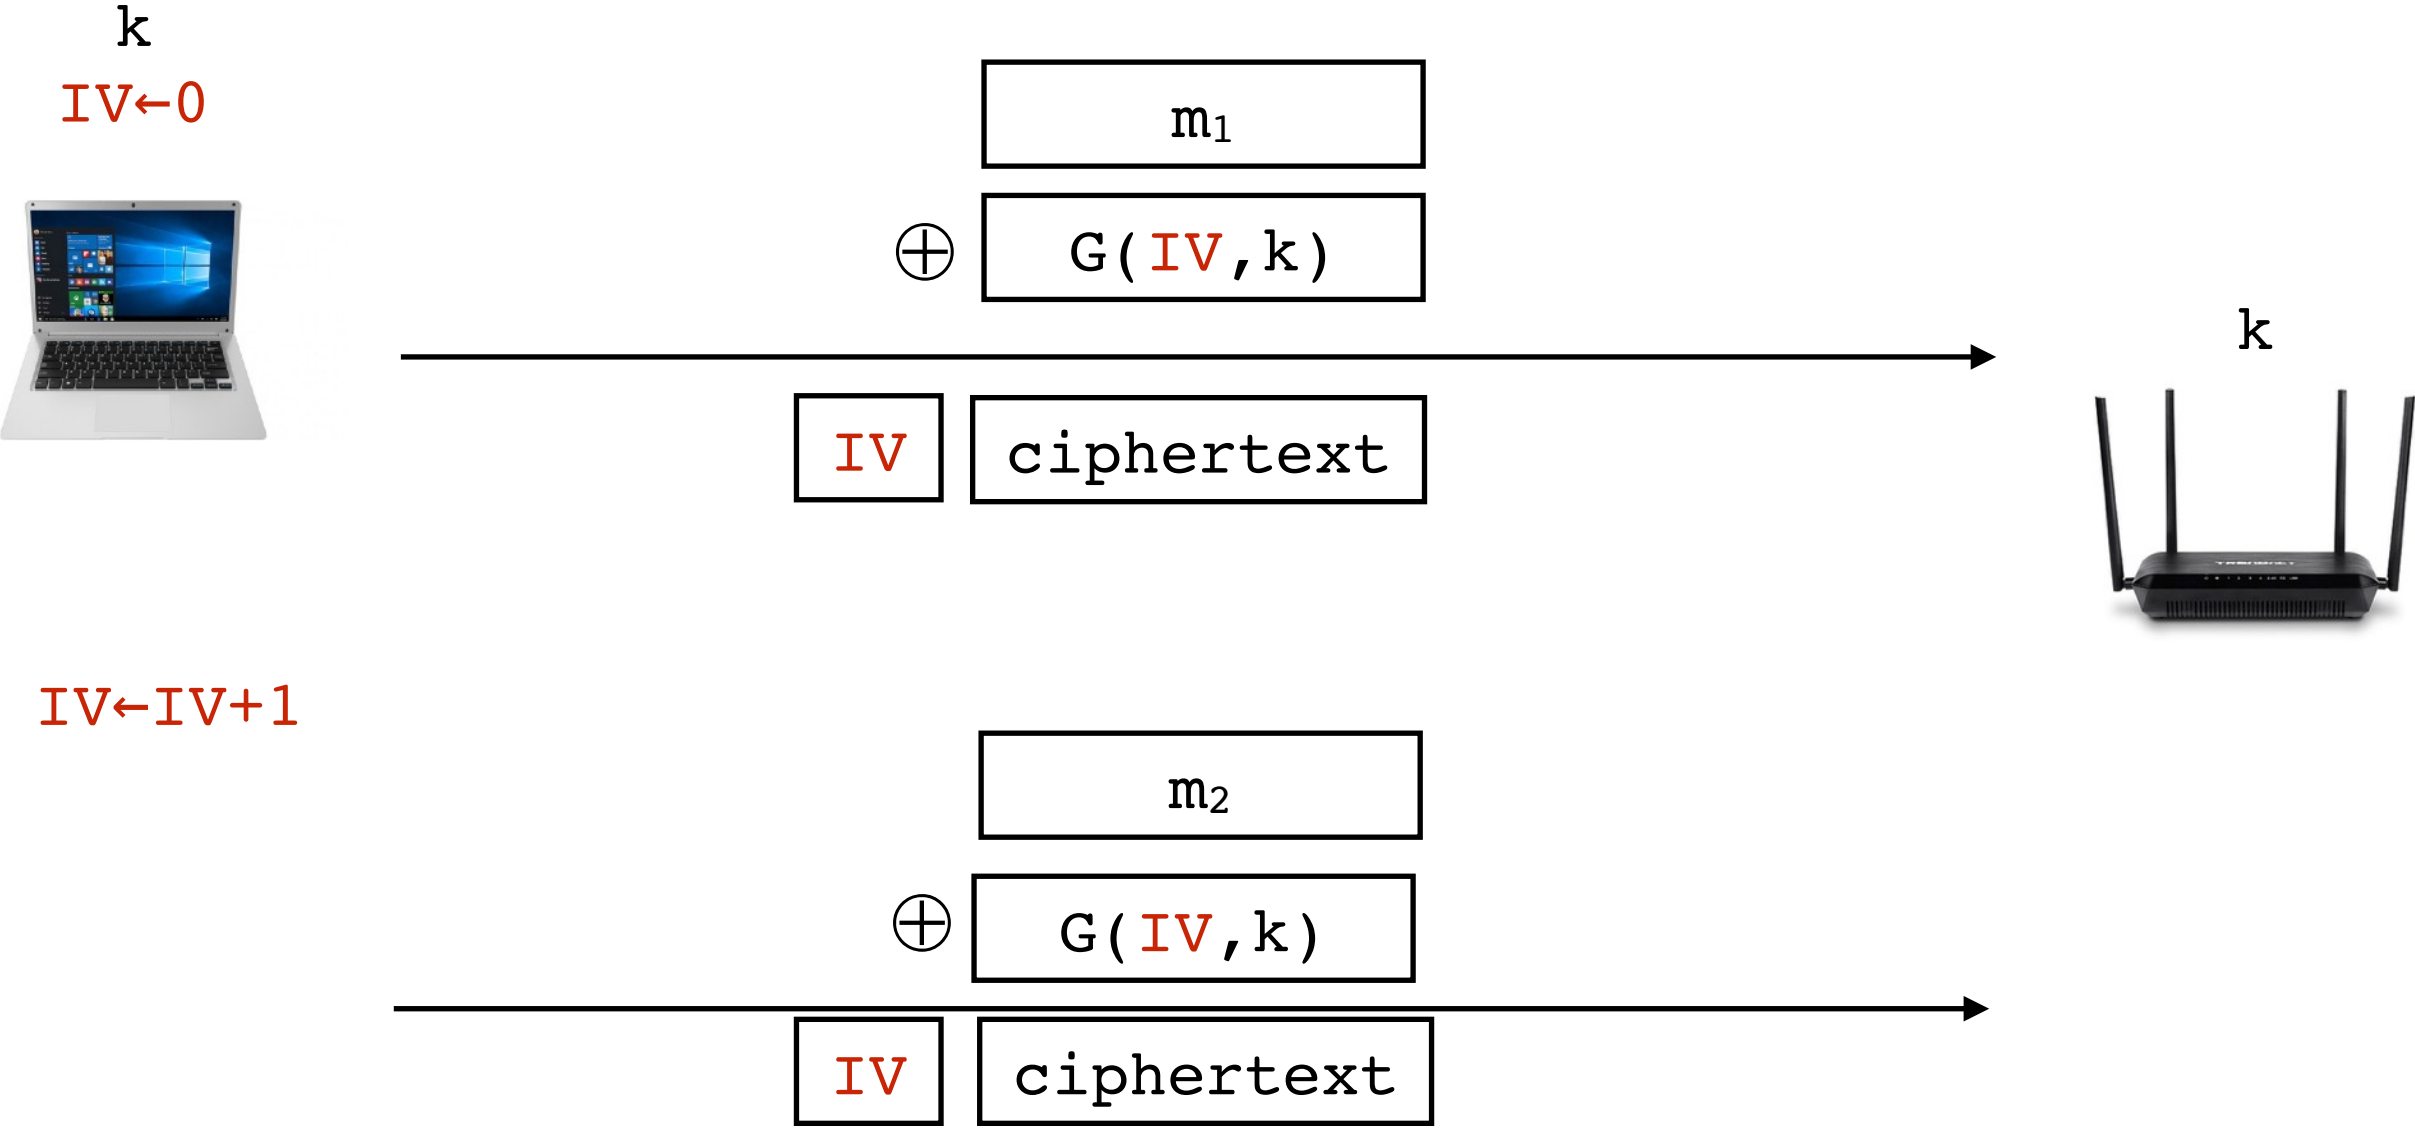

$G(IV,k)$: 11111010001000111010100101000101100100111100...

- “nonce” = “number once”.
- Usually denoted IV = “initialization vector”

Security goal: When k is random and unknown, $G(IV, k)$ should “look” random and independent for each value of IV .

Solution 1: Stream cipher with a nonce

- If nonce repeats, then pad repeats

Example of Pad Re-use: WEP

Warning: Broken

IEEE 802.11b WEP: WiFi security standard '97-'03

IV is 24-bit wide counter

- Repeats after 2^{24} frames (≈ 16 million)
- IV is often set to zero on power cycle

Solutions: (WPA2 replacement)

- Larger IV space, or force rekeying more often
- Set IV to combination of packet number, address, etc

Example of Pad Re-use: WEP

Warning: Broken

IEEE 802.11b WEP: WiFi security standard '97-'03

The screenshot shows the top of an Ars Technica article. The header includes the 'ars TECHNICA' logo and navigation links for 'BIZ & IT', 'TECH', 'SCIENCE', 'POLICY', 'CARS', 'GAMING & CULTURE', and 'FORUMS'. The article title is 'Serious flaw in WPA2 protocol lets attackers intercept passwords and much more'. Below the title, it states 'KRACK attack is especially bad news for Android and Linux users.' and is dated 'DAN GOODIN - 10/15/2017, 11:37 PM'.

Solutions: (W)

- Larger IV sp

- Set IV to combination of packet number, address, etc

parameters to their initial values. KRACK forces the nonce reuse in a way that allows the encryption to be bypassed. Ars Technica IT editor Sean Gallagher has [much more about KRACK here](#).

Issues with One-Time Pad

1. Reusing a pad is insecure ✓

Use unique nonces

2. One-Time Pad is *malleable*

3. One-Time Pad has a long key ✓

Use stream cipher with short key

More difficult to address; We will return to this later.
